

INTRODUCTION

After a great power struggle that makes Dallas, Dynasty and Falcon Crest look wet, I have at last got control of this part of "The Mag."

Steve has gone back on the road as a rep for us, a job he loves, thus leaving poor old me to guard the fort!

Well, enough of the waffle and on with the show! This months isue has a special feature on adventures, for some unknown reason people of late seem to be getting into these games for a little mental stimulation, and I'm glad to say that many software houses are writing them to keep up with the demand.

Also in this issue is a special look at random numbers, this topic is a little more technical, but not TOO technical, so hopefully those of you who are not of a technical nature might find it a little edible, and those who are quite technical should find it quite enjoyable.

Anyway, that's that for the time being, I hope you enjoy The Mag.

Michael Howard PROGRAMMER/

TECHNICAL SUPPORT

IMPORTANT NOTICE

Please note that this magazine is actually two magazines in one. We apologise for it's late arrival, but it was beyond our control.

It is important to note that this is **YOUR** magazine. So please send in any programs that you have, be them small or large, complex or simple . . . it matters not. If someone sends in a program and someone else learns from it then it has been worth it! To be quite frank I could name ten people in the UK, and three in New Zealand who now make a lot of money through writing programs, and they all started by writing a few simple programs and having them published in computer magazines!

SO GET WRITING!

LETTER'S TO

THE EDITORA

DEAR EDITOR

I am having a spot of bother with the program "Jet Ranger". Firstly I keep getting a Statement parameter error, and when I look at lines 1 and 2, they are all jumbled up. Could you please help.

Sid Bruce, Wellington

DEAR SID

The error you are getting is due to a typing error on your behalf, check that all the lines with DATA at the start contain only the digits 0,1,2,3,4,5,6,7,8,9,a,b,c,d,e and f. It is possible that you have accidently placed a O (the letter) instead of 0, or perhaps an I instead of a 1.

The lines 1 and 2 should get jumbled up, as this is where the machine code for the program is stored.

DEAR EDITOR

A couple of months ago I sent in a cassette to you, and I have not received it back . . . where is it?

Henry Hunter Dunedin

DEAR HENRY

You are not the only person suffering from this, I am sorry to say. But the reason for so many unreturned tapes is simple, I get about 20 tapes a week for review, and 19 out of that 20 are not marked, so it makes it next to impossible to identify a cassette. The moral to this story, is if you wish to send a tape for evaluation, and wish to get it back, then please put your name and address on the cassette, as well as the title of the program.

DEAR MICHAEL

I wish to set up my own software house selling some of the programs I have written, could you please tell me of how I would do this.

Jane Harrison Browns Bay

DEAR JANE

Here is how to do it:-

- 1) Make sure that the program is of good quality.
- 2) Buy some good quality C-10 cassettes, or a size to suit. Make sure that they are of the "Low Drop Out" kind.
- 3) Make copies of say, 40, of the program and send one to me along with your address and I'll review it in the mag.
- 4) Get some inlays printed.
- 5) Go to your local dealers and ask them to stock the program for you, on a "Sell or return" basis. This means that if the dealer doesn't sell the program then he has the right to return the program back to you, for a refund.
- 6) You could perhaps get the retailer to stock the program on your behalf, in other words, he doesn't buy the program off you, he just displays it for you and he gets a small percentage at each sale.
- 7) Advertise in the mag. Really cheap!!

One important thing is to make sure that the program is 100% guaranteed to load!

I hope that this has given some helpful advice to budding programmers.

DEAR EDITOR

This is just a note to say that the mag has now become the way I, and many others I know, like it . . . full of programs and interesting news. Keep up the good work.

Geoff Steele Hamilton

DEAR GEOFF

Thanks a lot for the compliments. You'll love this issue!! Have any others got any criticisms of the mag, don't forget it is your mag!

Software Reviews and News

It's funny how all of a sudden some **REALLY** great software is available, just when people were crying out for more! So without further ado, here are a couple of reviews.

AEROBAT . . . 32k only

Just about everybody has been yelling out for a flight simulator, well here it is! This program allows you to simulate the flight of a small light aircraft called a Cessna 152 Aerobat.

When the program is running, you are confronted with a cockpit view of the aircraft this includes the view outside the cockpit, a compass, a vertical speed indicator, fuel guage, power guage, artificial horizon, an air speed indicator and an alimeter. At first you are on the ground on a runway, you slowly accelerate and the runway starts to move as you get faster and faster, then when you reach a safe enough speed, you pull back on the joystick and up you go, flying!

When in the air, you have many controls over your craft, you control the ailerons, these control the roll of the aircraft. Elevators control pitch, ie up and down movement, and the rudder controls yaw (no not yawn!) this is sideways swing. The breaks are really neat, you can sit on the runway and build up to full power, then let the breaks off and just about catapult yourself along the runway!

The most impressive part of the program has to be the graphics, everything is in full 3D wire (called Vector graphics) graphics. To the South East of the airfield is a lake and on this lake is an arched bridge, and it is in fact possible to fly under the bridge! In full 3D!

It is also possible to do aerobatics such as loops, stalls, stall turns, rolls, barrell rolls and combinations of the above.

All details are accurate such as the inability to stay upside down for too long as the fuel system does not have the ability to function upside down for prolonged lengths of time.

Note that the program is for the 32k model only.

To sum up, this is a truly remarkable game and well worth the money.

It is available now from Poseidon Software, CPO Box 784, Hamilton.

Burglar Bill

An absolutely stunning program with amazingly smooth animated graphics. If any of you have seen the program Jet Set Willy on other computers and liked it then this is the game for you. It is, of course 100% Machine Code, as are all programs these day! And this leads to a really pleasurable and enjoyable game.

The game goes something like this . . . you are a burglar called Bill, pretty obvious really! And you decide to case the place. Well that sounds quite easy, but all is not as it seems, inside the houe there are many wierd and wonderful creatures running around the place, you must dodge these and get hold of the artifacts that the house holds. This is in essence a Ladders and levels type game where you have to run upstairs and downstairs dodging this-that-and-the-other . . . in general good wholesome stuff! I can't recommend this game enough. It is available from Poseidon Software.

Sega Mon

A must for all serious programmers. A monitor is used to de-bug machine code programs and let's you patch up the mistakes. You can set registers, inspect them and test them at any time that you want. Once again this is another excellent product from Poseidon Software, although it's use will be only by proficient machine code programmers.

Sega Word 3

This is the program that all you disc drive owners have been waiting for . . . a professional word processor. This program let's you copy paragraphs, delete paragraphs, format the document, force end of pages, display menus, set printer controls, kill documents, set margins, move paragraphs, print documents, read in documents

and save documents, search for a word etc et. The disc that comes with the program has a bonus program on it for Cashbooks, it is only the instructions for using the program and the cashbook is not in the country yet. Getting back to the Word processor, it is a breeze to use and extremely quick. In fact I would say that this is one of the best wordies this side of Pluto!

For more info get in contact with Poseidon Software (again!!)

Saturn Earth Demo

by W.G. Wells

You may remember that in the last magazine there was a little program that let you draw a small picture of the planet Saturn. Well, this program is a modification of that.

Mr Wells reckons that he has learned a heck of a lot from re-writing the program, which as far as I'm concerned is what this mag is all about!

Secret Writing . . . Explore the craft of cryptography

Secret writing, or cryptography, is the craft of hiding information by by converting into info into a code that looks really ridiculous, thus leading the person who is being exceptionally nosey to think that the text is a load of old cobblers. Only by using the correct password can the reader unlock all the secrets that you placed in the message.

This month I am going to present a program that turns your Sega into a coding machine, using a simple, but effective, and acient cryptographic technique known as Caesar cipher.

The Caesar cipher got it's name from the ol' Roman called Julius Caesar (you know "Ides of March" and all that!). The way the cipher works is quite simple, basically, every letter is shifted by a certain amount, the amount is called the key. For instance, with a key of say, 3, the letter A is shifted forward to become D, and B becomes E etc. If we reach the end of the alphabet, then we simply continue to the start of the alphabet. Thus, using the same key of 3, the letter Y becomes B. Keeping with a key of 3, the message:

THE APPLES ARE RIPE

becomes the coded message:

1 REM MH

WKH DSSOHV DUH ULSH

To decode the message, we shift each and every letter in the coded message back the same key. In this case, we shift W back 3 to get T, K back 3 to get H and so on and so forth.

Unfortunately, the shifting of letters back and forward is extremely boring and tiresome. But lo and behold, computers are designed to do boring and repetitive tasks. So here follows a short prelude of how the program works.

Let's start with a short description of the cipher machines duties. First it asks you to type in the key, select encoding or decoding, and type in the message. The Sega picks out the first letter of the message, encodes or decodes that letter, and prints the coded letter. The computer picks out the next letter in the message (ignoring all spaces and punctuation) and encodes or decodes that letter. It repeats the process until no more letters are left to be coded.

The program

The program is quite straight forward and is written entirely in BASIC. It uses four special BASIC functions to

accomplish the ciphering. All of these functions perform operations on strings (a sequence of letters and other characters).

Michael Howard

LEN measures the number of characters in a string. For instance, PRINT LEN(M\$) prints the length of the string M\$. The program uses LEN to determine the number of letters in the message to be coded.

MID\$ picks out one or more letters from a string. For instance, MID\$ (message, position, length) gives us a portion of the message starting at the stated position and running for the stated length. Eg;

If M\$5"HELLO MUM!"

MID\$(M\$,2,9) = "ELLO MUM!"MID\$(M\$,3,3) = "LLO"

In the program, MID\$ picks out one at a time the letters of the message to be coded.

ASC gives us the numeric position of the character in the Sega's alphabet. For instance ASC("A") gives 65, this is the position of the letter "A". This may seem illogical, but don't forget, your micro computer has a vast alphabet of 256 letters and characters, the letter "A" is number 65 in that alphabet. The alphabet that is in the computers memory is called ASCII (American Standard Code for Information Interchange. Other examples are ASC("M") is 77.

CHR\$ is the opposite function of ASC, you supply a number and it gives the character. EG CHR\$(65) gives the letter "A".

The following variables have been used in the program:

VARIABLE	DEFINITION
LB UB	ASCII position of letter "A" ASCII position of letter "Z"
K	key
CH\$	choice of encoding or decoding
M\$	message
P	indicates current letter
X\$	letter pointed to by P
Y\$	encoded or decode letter
YP	ASCII position of Y\$

The program is listed below:

```
10 1b=65
20 ub=90
30 PRINT "Secret Writing Machine"
40 PRINT
50 INPUT "Enter the key (1-25) ";k
60 IF k<1 OR k>25 THEN 50
70 INPUT "Enter E to encode, or D to decode ";ch$
80 IF ch$<>"e" AND ch$<>"E"AND ch$<>"d"AND ch$<>"D" THEN 70
90 PRINT"Enter a message"
100 INPUT m$
110 IF m$="" THEN 90
```

```
120 FOR p=1 TO LEN(m$)
130 \times \$ = MID\$ (m\$, p, 1)
140 IF x$>"A" AND x$<"Z" THEN 170
150 y = x =
160 GOTO 240
170 IF ch$="D" OR ch$="d" THEN 210
180 yp = ASC(x$)+k
190 IF yp>ub THEN yp=yp-26
200 GOTO 230
210 yp = ASC(x \$) - k
220 IF yp<1b THEN yp=yp+26
230 y \triangleq CHR \triangleq (yp)
240 PRINT y$;
250 NEXT p
260 PRINT
270 PRINT"Le End (more French!)"
280 END
```

Solitaire

In this game or puzzle, call it what you like, 48 checkers are placed on the two outside spaces of a standard 64 square chess board as is shown in the program.

The object of the game is to remove as many checkers as possible by diagonal jumps (as in Draughts or Checkers). It is easy to remove 30 to 39 checkers, a challenge to remove 40 to 44 and you must be brilliant to remove 45 to 47. The numbering of the board is as follows:-

```
10 11 12 13
      18
            19
                  20
                        21
                              22
                                    23
                                          24
25
      26
            27
                 28
                        29
                              30
                                    31
33

Random Words Program 1

Have you ever written a program, and then thought, "Now what could I call the main character?", or "What should I call the land", I'm sure you know what I mean. Well, hopefully, this little gem of code will help you in deciding such nomeclature (a fancy name for naming!).

All you do is enter the program and run it, after a word is printed on the screen just press a key and another word will be printed. The program as it stands will probably not give many words, but I guarantee that it will give you, some good ideas for new words.

```
10 \times = RND(-1)
20 DEF FN rn(x) = INT(RND(8) *x) + 1
30 DATA b,c,d,f,g,h,j,k,l,m,n,p,q,r,s,t,v,x,w,y,z,ch,sh,st,ts,ny,yn,sl,nd,-1

Random Words Program 2

Here is another program for generating random words. Just run the program, and it will produce a matrix of letters, now just link together some groups. of letters to make up a word.

In my opinion, this program is better than the first, due to it's lack of complexity, flexibility and ease of use.

```
10 CLS

20 FOR a=0 TO 20

30 FOR b=0 TO 30

40 PRINT CHR$((RND(8)*25)+65);

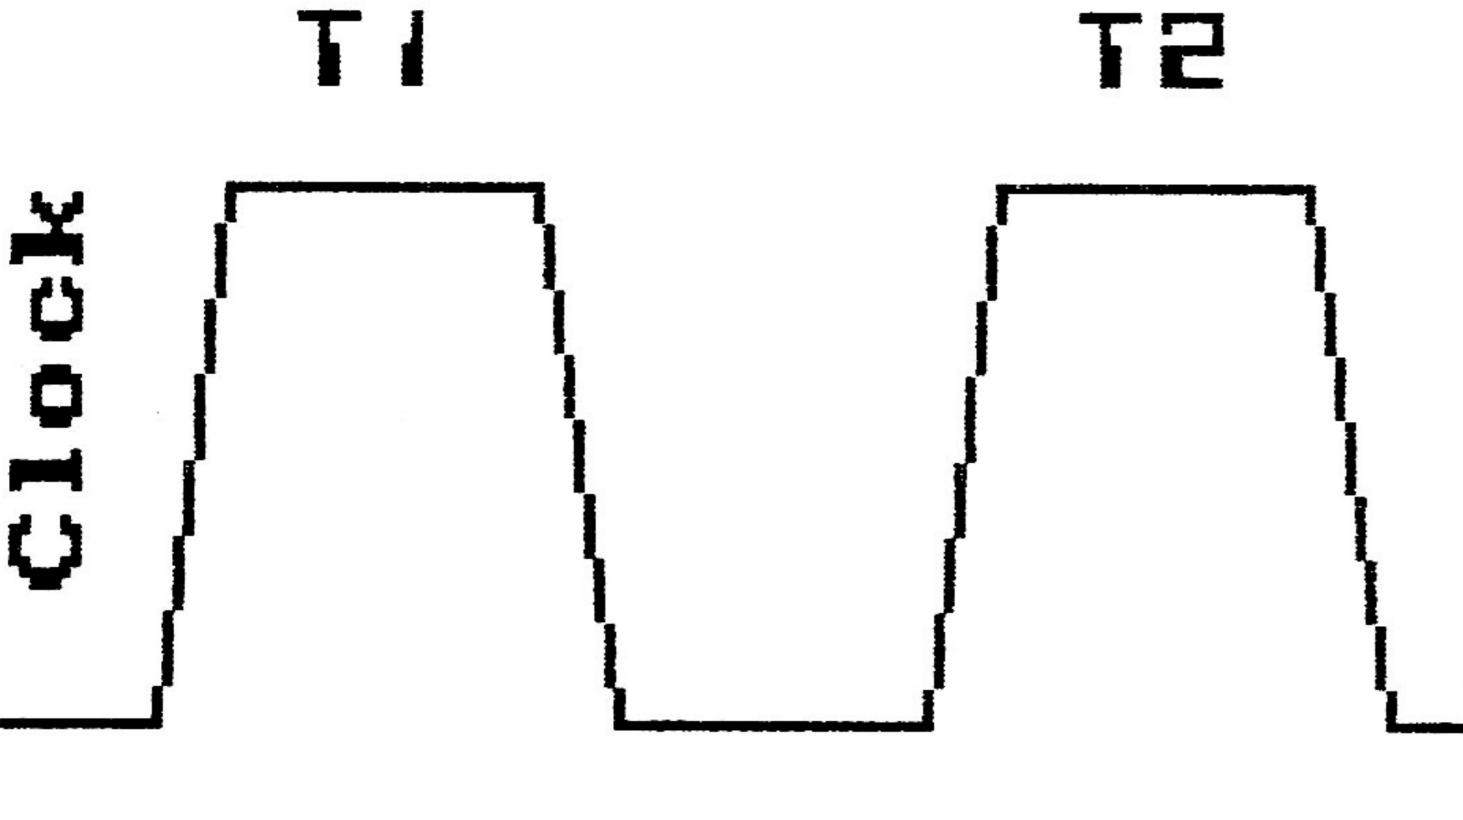

50 NEXT:PRINT:NEXT
```

Random Numbers from Machine Code

... Michael Howard

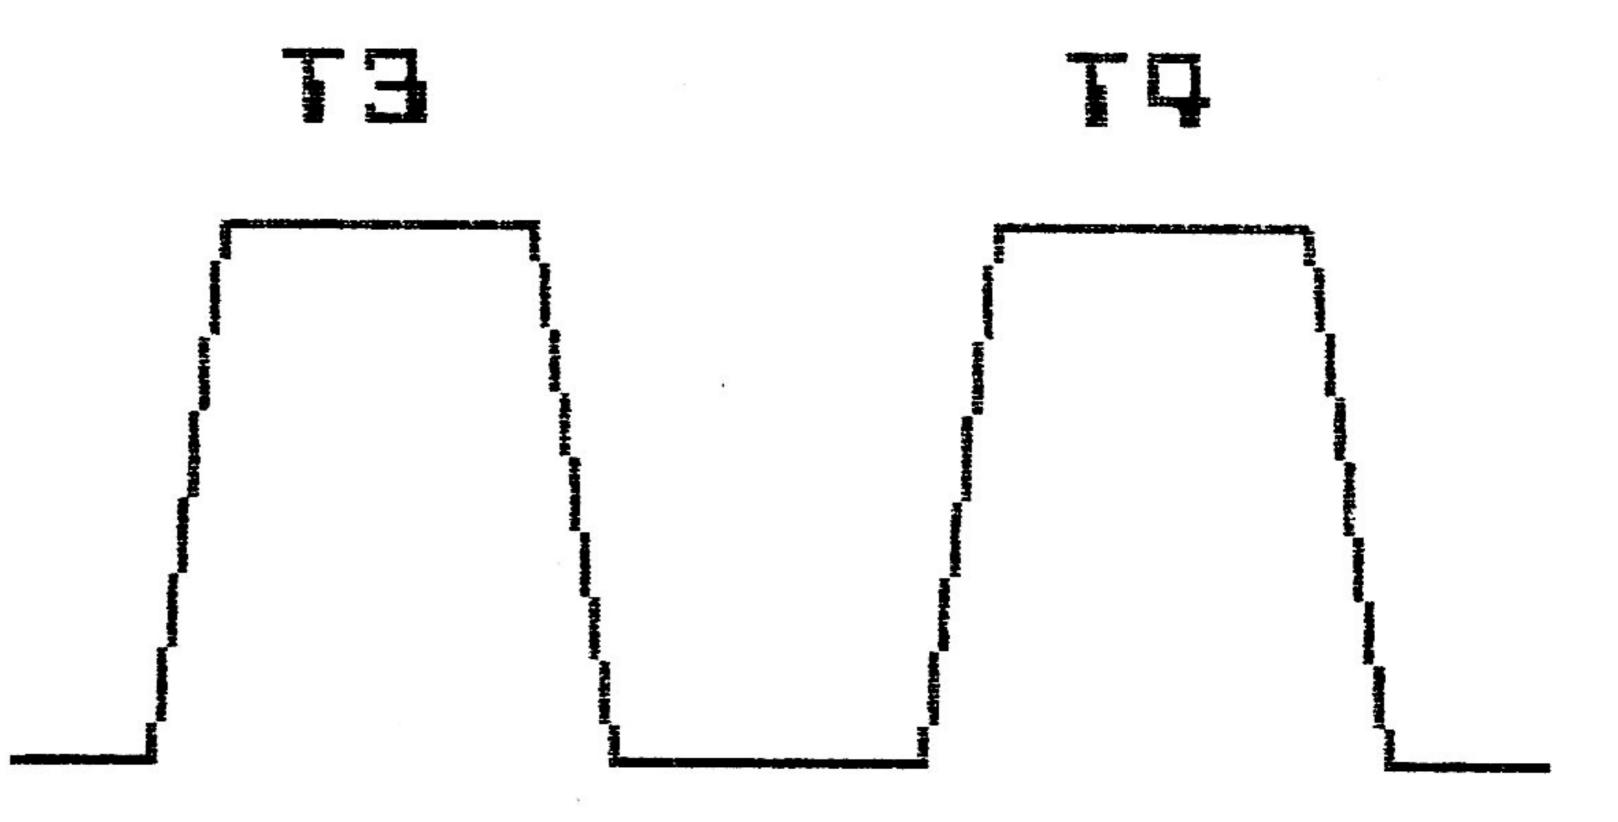

Generating random numbers from machine code is not at all easy, and Z80 users may be tempted to seek a solution by using the memory refresh register to generate them. But firstly, let me explain a little about memory and how it works (I bet you're wondering what memory has to do with random numbers!).

Compute memory is divided into two parts, ROM and RAM. The Read Only Memory is the Sega's "handbook", every program that you write has to be cross referenced with the ROM to see what to do next and how to execute every BASIC instruction that you write. The RAM or Random Access Memory, is where your programs are stored. Now RAM can be broken down into two types, Static and Dynamic. Whenever you store some data or a program in static RAM, the data stays there until you turn the power off, the disadvantage of static RAM is that the chips are quite large, so they are not used all that often. On the other hand, dynamic RAM chips are small, and can hold a lot of information on each chip. The only drawback of dynamic RAM chips is that they "lose" their memory after about 1 second! So every 50th of a second, the Z80 inside your Sega "updates" the contents of some of the RAM (because all the RAM in your computer is dynamic), this "updating" is called REFRESHING. Now the Z80 has to keep track of what part of the memory it is refreshing so that it does not refresh one part of memory too often and another part never gets refreshed. To keep track of where the Z80 is refreshing, the "memory refresh register" is used. The Refresh Register is in fact an 8-bit register just like registers "A", "B", "C" tetc etc . . . but only 7 bits are used, after every machine code instruction is executed the contents of the Refresh register are incremented by one, then that bank of memory is refreshed. As a very simple example, if R (the refresh register) holds a value of 42, then bank 42 will be refreshed. When the next instruction is executed, R will hold 43 and bank 43 will be updated, and so on and so on. If you look at the diagram below, you will see how the memory refresh is timed, T1 and T2 and two clock cycles, the clock is a QUARTZ crystal that vibrates about 4 million times a second!, during T1 and T2 an instruc-

Instruction cycle

tion is operated on by the Z80 (the CPU inside your Sega, CPU means Central Processing Unit), but during T3 and T4, dynamic memory chips are refreshed.

Memory refresh cycle

Now, as I stated before, you are probably wondering what on Earth, memory has got to do with random numbers, well the answer is the R register. The intended use of the register is to keep track of the memory refreshing, but it is possible to be read the register by use of the LD A,R instruction. The result in bits 0-6, will be a number in the range 0-127. If the read is called at a moment dependent on some action outside the processinf system, such as a key being pressed, the number obtained will vary at random.

For most purposes, however, a 0-127 range is excessive. If we want a number in the range 1-6, to simulate a dice being thrown, you could use AND 7 to cut the range down to 0-7 and ignore values of 0 and 7 and looping back to repeat the LD A,R instruction.

You could do that, but it would be unwise. Think about it. The loop to the repeat of LD A,R will contain a predictable number of instructions, so the change in the R register will be equally predictable, and the last thing we want with random numbers is predictibility! What we could do is as I mentioned before, is read the keyboard for any action and when a key is pressed get a number from the R register, but this is really clumsy, without an outside trigger such as a key being pressed, no numbers will be generated. So what do we do?

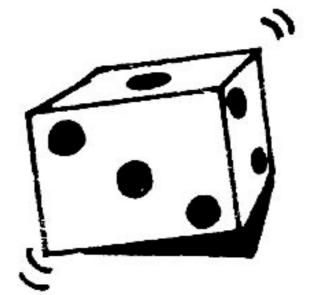

BREAK THE LOOP

All this messy random number business leads to only one efficient solution. If we want a number in the range 1-6, we would multiply the memory refresh register with 6, divide by 128 and add 1 to the result, so a bit complex? Not really! The little program below shows how it is done in machine code:

:> : : :	nmemonics LD HL,0000 LD D,0 LD E,N LD A,R ADD A,A LD B,7 RLC A JR NC ADD HL,DE ADD HL,HL DJNZ LD A,H INC A RET	06,7	hex data 21,00,00 16,0 1E,N ED,5F 87 07 30,1 19 29 10,F9 7C 3C C9
-------------------	--	------	--

In this program, the number range is placed in the E register. So if we want numbers in the range 1-6, then we would load E with 6, ie LD E,6 and a number in the range 1-6 will be in the A register (accumulator). So all in all this is a really neat little random number generator that is extremely versatile and efficient. Well that just about covers the random number subject in machine code.

SIMULATING DICE THROWS [• .]

A final point on random numbers concerns the simulation of dice throws. If two dice are to be thrown, it is not correct to generate a number from 1 to 12, with a equal value of each. Two random numbers, each in the range 1-6, must be generated, and their sum is the new random number. Why? As Fig 2 shows, there is only

one chance in 36 of getting a 2 or 12 whilst there are six chances of getting a 7.

Random numbers are useful, sometimes even essential, but you have to think about them very carefully at times so make sure that you know what you are doing when messing about with them.

1st dice							
:	1	2	3	4	5	6	
1:	2	3	4	5	6	7	
2:	3	4	5	6	7	8	
3:	4	5	6	7	8	9	
4:	5	6	7	8	9	10	
5:	6	7	8	9	10	11	
6:	7	8	9	10	11	12	
Fig 2. Two dice combinations							

PS: I know that this article may seem a little heavy, but it has to be really, so please accept my apologies all those who know not of Machine Code!

COUNT THOSE BANDS ON RESISTORS

Many people have a lot of trouble trying to work out what those bands mean on resistors, sometimes they can be confusing and lead to lots of human error. So I thought I would write a program to allow you to convert the coloured bands on resistors to a more digestible form.

When you run the program you will be asked to input the three band colours, when you have entered the relevant data the computer will give you the resistance of that resistor and it's tolerance.

If you want to remember the order of the colours remember this little rhyme:

"Black Baron Runs Over Young Girl Bellowing Vicious and Gruesome Words"

All you electricians out there should find this routine extremely useful.

Just for general interest here is a little note for those who don't know about resistors.

A resistor is a small cylindrical shaped device that has two wires popping out of the end. They are used in electronic circuits to stem the flow of an electric current, the reasons for doing this are quite complex at times. Now, sometimes you may wish to stem the flow to a high degree, and sometimes to a small degree, and to alter the flow, you just alter the resistance of the resistor, the higher the resistance, the less power gets through, and vice versa. The way you can tell the resistance is by the banding on the resistor, certain combinations of colours give certain resistance values. Now, one of the problems is reading those bands of colour and remembering the values, so that is what this program is all about.

For reference, bands 1 and 2 determine the resistance, and band 3 the tolerance ie, how accurate the value given on the resistor is.

Resistor Eddy

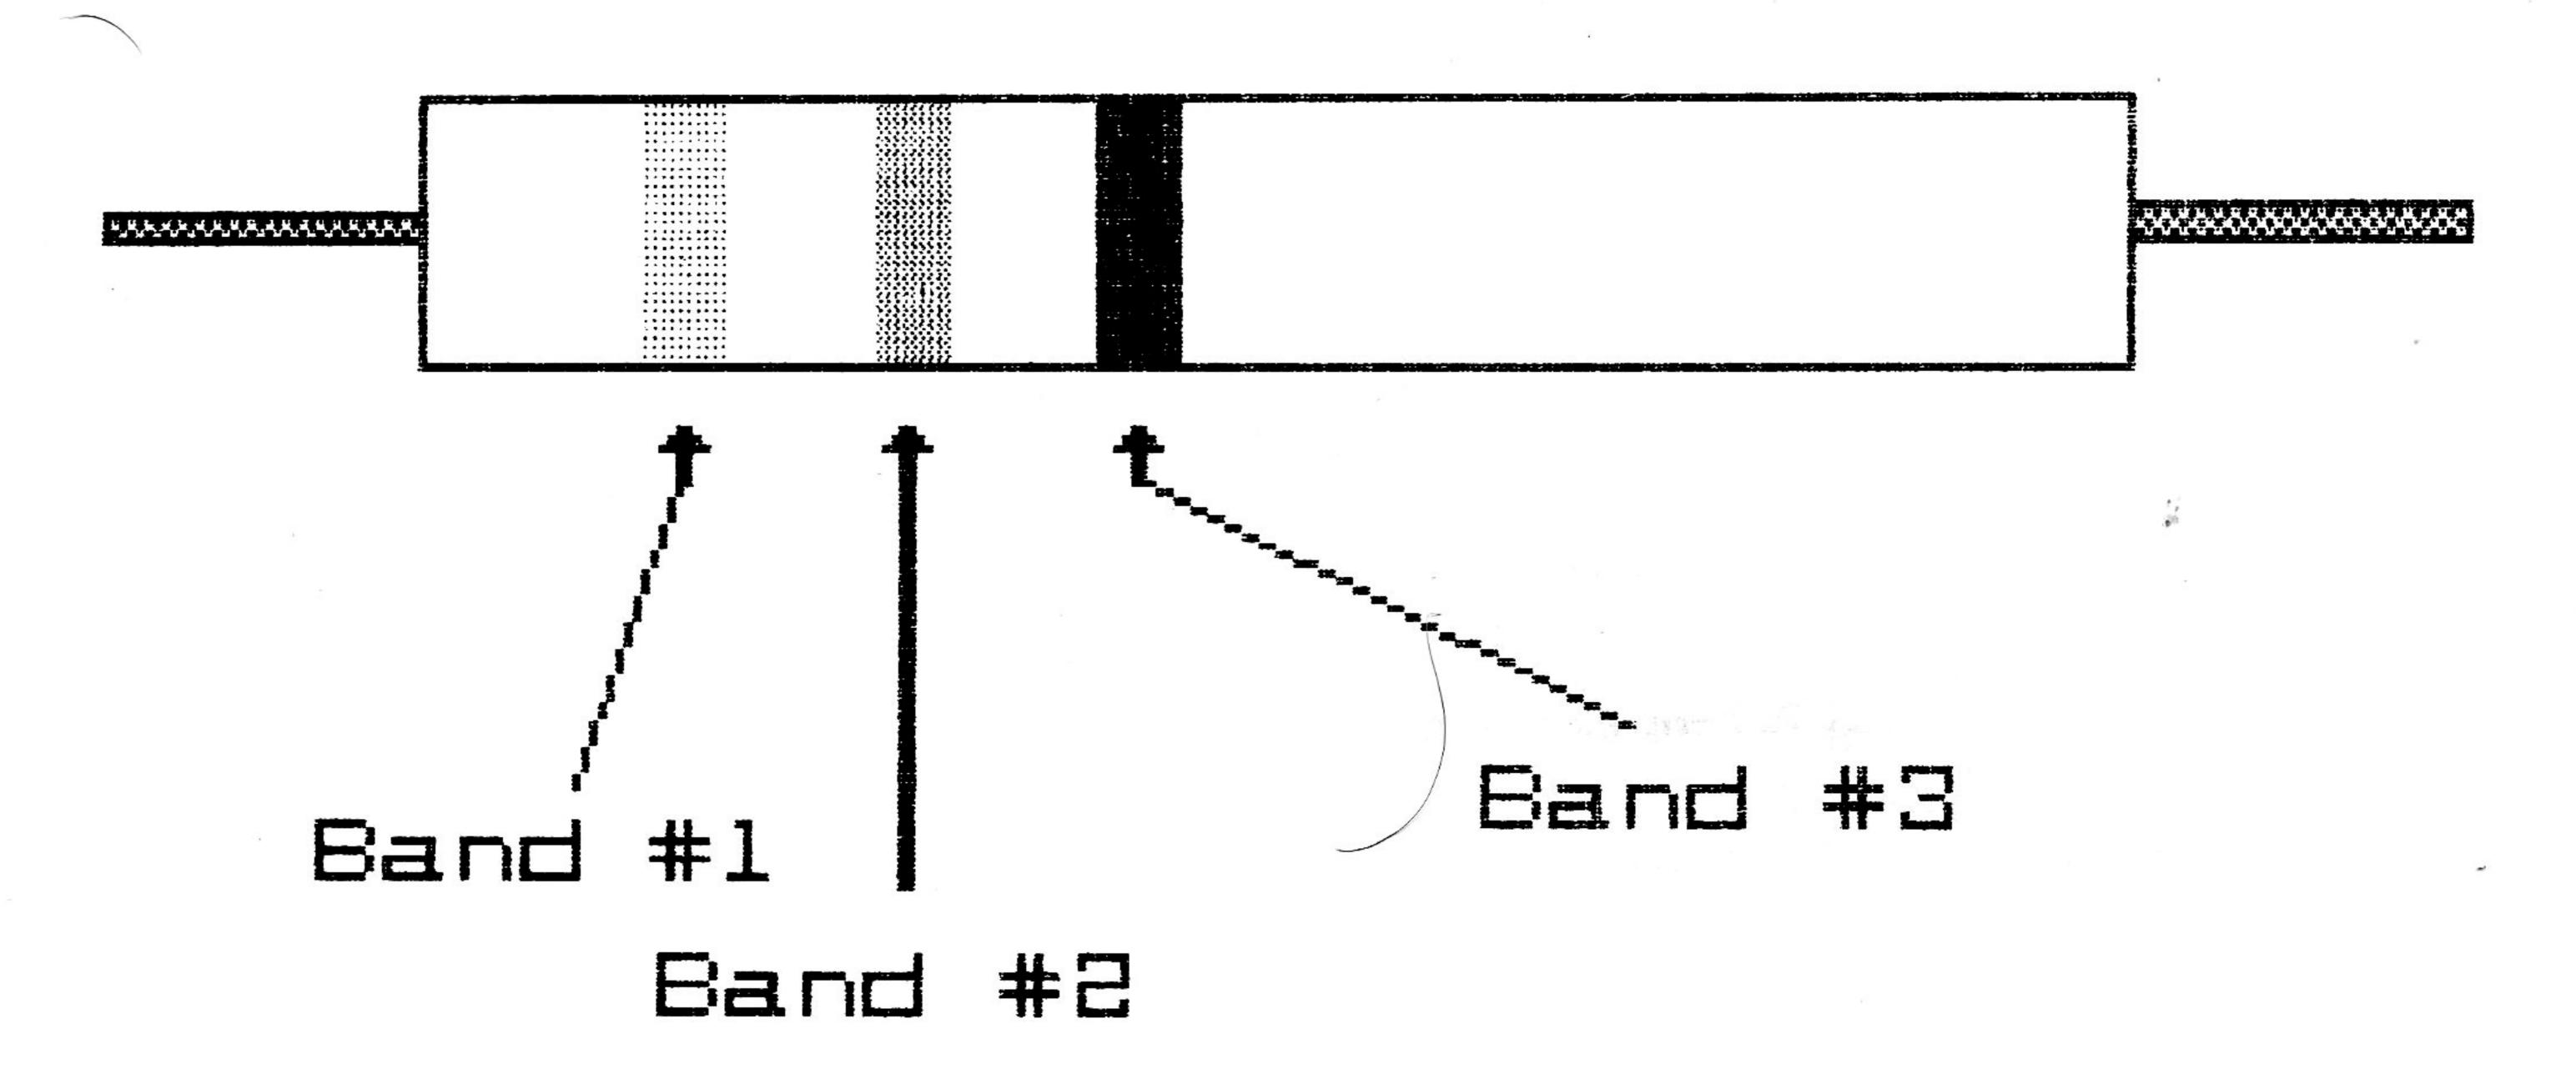

Fig. 1 What a resistor looks like.

The colour of the Bands determine the resistance of the resistant.

The Sine Wave

Did you ever go to a computer show and see a computer waiting to do a demo for you? It was one of these moments that made me decide to do my own simple, yet interesting demo. Here it is:

If you have the SP-400 printer plotter then alter line 130 to:-

130 LPRINT TAB (A);

Try to limit your texts to less than 6 characters.

```
10 INPUT "ENTER A WORD....."; A$
20 INPUT "NOW ENTER ANOTHER..."; B$
30 B=0
40 FOR T=0 TO 40 STEP 0.25
50 A=INT(15+15*SIN(T))
60 PRINT TAB(A);
70 IF B=1 THEN 110
80 PRINT A$
90 B=1
100 GOTO 130
110 PRINT B$
120 B=0
130 NEXT T
```

If you have the SP-400 printer plotter then alter line 130 to:-

an inportant hotice

As you may have noticed, this issue is a bit late. Well the reason for this is simple....

There is a lack of programs from you lot!!

So PLEASE, precise, allawsa, please send some programs in! The more you send in the better.. It's your way to fame!!

You can turn the page NOW!!!!

King of the Islands

Phil Tottle

This is one of the more comprehensive, difficult and interesting land resource management games going! If you have never played this type of game before, then I suggest that you start off on an easier one, like the game in More than 50 programs for the Sega SC-3000.

In this game, you are the King (or Queen for that matter!) of a small island called **Esterlouisia**, which measure 70 by 30 kilometres. Your job as the boss is to decide upon the budget of the country and distribute money to your countrymen from the communal treasury.

The money system is Vanders; and each person needs at least 100 vanders a year to survive. Your country's income comes from farm produce and tourists visiting your superb forests, fishing and hunting facilities. Part of your land is arable farm land but it also has an excellent mineral and may be sold to foreign industry for strip mining. Industry import and support their own workers. Crops cost between 10 and 15 vanders per square mile to plant, cultivate and harvest. Your goal is to complete an 8-year term of office without major mishap. Good luck. A word of warning though . . . it isn't easy!!!!!!!

```

1 PRINT "RUSSIAN ROULETTE"

Awai is an ancient African game played with seven sticks and thirty two stones or beans laid out as shown below:

	My Side						
	6	5	4	3	2	1	
My	000	000	000	000	000	000	Your
Home	000	000 2	000 3	000 4	000 5	000 6	Home
	Your Side					TE	

The board is divided into six compartments or pits on each side. In addition, there are two special home pits at the ends.

A move is made by taking all of the beans from any (non-empty) pit on your own side. Starting from the pit to the right of this one, these beans are "sown" one in each pit working in each pit working in an anticlockwise direction.

A turn consists of one or two moves. If the last bean of your move is sown in your own home you may take a second move.

If the last bean sown in a move lands in an empty pit, provided that the opposite pit is not empty, all the beans in the opposite pit, together with the last bean sown are "captured" and moved to the players home.

When either side is empty, the game is finished. The player with the most beans in his home has won.

In the computer version, the board is printed as 14 numbers representing the 14 pits.

The pits on your (lower) side are numbered 1-6 from left to right. The pits on my (the computer's) side are numbered from my left (your right!). Isn't this confusing?

To make a move you type in the number of a pit. If the last bean lands in your home, the Sega asks you if you want to go again, you, then enter your second move.

The computer's move is taken followed by a diagram of the board in its updated form. The computer always offers you the first move. This is actually an advantage for the computer!

This is a TRUE ARTIFICIAL INTELLIGENCE program as the computer actuall gets better at the game as the game continues, ie it learns from it's and your mistakes! And as it plays more games it gets to be just about impossible to beat!

10 REM MH

SPRITE GENERATOR

We all know that the Sega has some of the easiest sprites to use in the business, so to help you even more at trying to grasp the immense power of the Sega's sprites, here is a program that just about everyone has been asking for, A sprite generator.

When you run the program, a box will be drawn and a small menu will appear on the right of the screen, with a little message "Please wait".

Here are the options open to you:-

Arrow keys . . . Move the "blob" about the box. If you go off the edge then the "blob" will appear on the other side of the box.

Space bar . . . This lets you fill in a small pixel in the 16 by 16 block. If the pixel is already filled in then when you press the space bar you erase that pixel.

Carriage return key . . . This lets you see the shape of the object on the hi-resolution screen, and then goes back to the text screen, note that in the top right hand corner there will appear 4 lots of data, this is the data for the sprite.

F... This lets you flip over to the hi-resolution screen to see your shape again, after you have created it.

Q... This lets you invert a line across, in other words, if a horizontal line is blank, then after you press "Q" that line will be filled. It's easier to see what I mean by experimenting.

W . . . As above but inverts a line downwards.

I . . . Inverts the whole 16 by 16 grid, thus creating an inverse of your sprite.

G... Flip the sprite across, a bit like looking at the shape in a mirrow.

H . . . As above but flips the shape upwards.

E,S,D,X . . . Lets you move the entire 16 by 16 matrix in any director, ie E moves the shape up, S left, D right and X is down. The object of these keys is to allow you to centre a shape.

Z . . . This allows you to enter hex or decimal data, so you can see what a shape looks like just from the data. Eg; if a sprite appears in a magazine with the following data 001E23FAFDCB0199 then enter &H00, &H1E etc and this will then draw that sprite. Hex has to start with ?H.

C... Lets you copy the data and shape of the sprite to the printer. The printer must be the SP-400 printer plotter.

L... Lets you fill in a shape. Fills a line at a time. My only suggestion is to mess about with the controls until you get quite fluent in it. Oh, and by the way the "q", "2", "q", "3", "a" and "s" characters are in fact the characters that make up a box. Firstly press then "ENG DIERS" key, and then press the corresponding key, so where it says 2, just press 2, where it says q just press q, but make sure you, are using "ENG DIERS", you know that you are if the cursor is an asterisk "*;".

The Beginners Box of Bugs

I am having a few problems understanding the basic of BASIC, I know that this may seem a little stupid, but it just doesn't seem to make any sense!

BASIC has become the most widely used programming language this side of Pluto! And as such, is an important tool for all computer users.

The most effective way of learning a programming language is through actual practice. This little tutorial has been designed to teach BASIC through a few simple graduated exercises. It is written for all readers who have a minimum scientific or technical background and who want to learn through actual experience, by studying realistic examples, how to program in Sega BASIC.

Anyone can learn to program in BASIC, by working through some practical exercises. This tutorial will demonstrate that programming is not just for professionals. Starting with a simple exercise you will be taught the rudimentry instructions, what they do and how to use these with the rules of BASIC. No prior knowledge of BASIC is needed.

The reason for this little bit coming about is due to the inadequte little blue book that comes with the Sega, it is a good reference manual, but lousy to learn from!

First Program . . . A Simple Equation

Imagine the following equation:-

Weight in Pounds $= 14 \times \text{Weight in Stones}$

This simple program converts weight in stones to weight in pounds, by multiplying stones by 14.

The program to do this may look like this:-

10 INPUT S

Read in weight in stones

20 P = 14 S

Calculate weight in pounds

30 PRINT P

Print out the result

40 END

Although simple, this program brings up several points about the format of a BASIC program:

- Each line has a line number
- Each line carries an instruction
- The read instruction, ie., the **INPUT** instruction, is used to get information into the computer.
- In the instruction on line 20 multiplication is represented by an asterisk.
- The program is terminated by an **END** instruction, but this is optional.

To enter the above program just type out the line number, then a space and then type in the instructions on that line. When you have finished typing in the data for that line press the **CR** key (this is the big one just left of the four arrow/cursor keys), then type in the next line. When you have typed in all the program lines type in **RUN** and then press the **CR** key.

When the program is run, you will see a ? on the screen. This question mark means that the computer is waiting

for some information. In this case it is expecting a number that is a weight in stones, as an example enter the number 11, in other words 11 stones in weight. Now pres the \mathbf{Cr} key.

Note that when you want to give the computer some information you must press the **CR** key after you have typed in the data. In this case after you have typed in 11 you press the **CR** key.

Okay, now that you have typed in the data and press the **CR** key the computer will chew on the info and spit out the number 154. In other words 11 times 14 is 154, 11 stones is equal to 154 pounds.

So what has the program done? Well to start off, line 10 has prompted the user (that's you!) to input a number.

Line 20 then works out the value of your input into pounds of weight.

Line 30 then prints out the value of your weight in pounds.

The last line tells the computer to stop, this line is optional, but most books on programming reckon that you must always put an **END** in for good measure, so to keep in line with these books, I've put in an **END!**

As the program stands, it is mathematically correct, the major problem is that it is about as **user friendly** as a brick! The words **User Friendly** mean just that . . . a program that is user friendly is easy to use from the user's point of view (don't forget a user is a person like yourself). I'll now show you a version of the same program that is a little more user friendly.

Firstly, type in **NEW** and then press the **CR** key. NEW wipes any program that is in the computer's memory. Now enter the following program:-

10 CLS

20 PRINT "A Program to convert stones": PRINT "to pounds (weight)"

30 PRINT:PRINT

40 INPUT "Enter a weight in stones";S

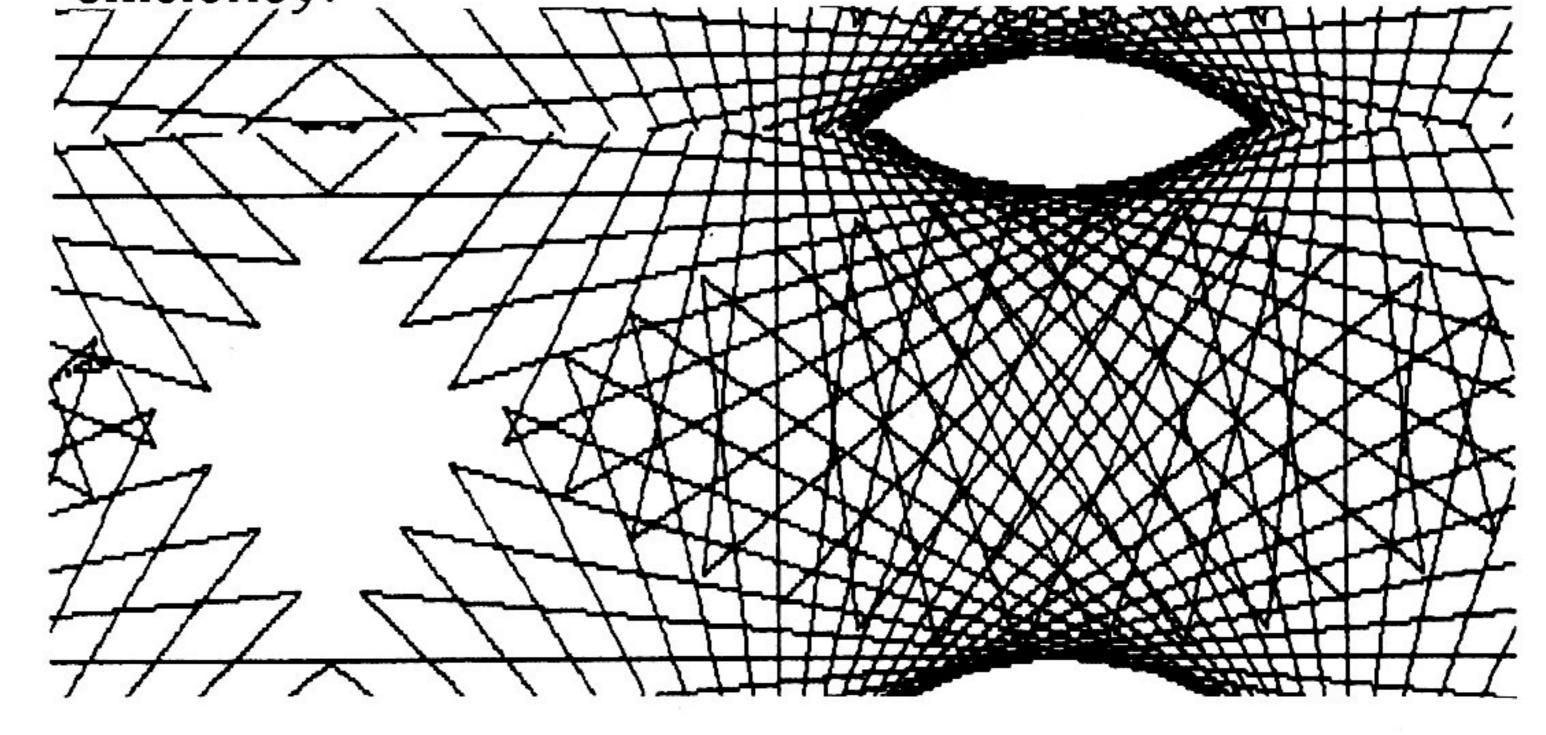

50 P = 14 * S

60 PRINT:PRINT

70 PRINT S; "stones is equal to ";P; "pounds"

80 END

Now, this program may appear to be a little bit too complex for the job in hand, well maybe it is, but that does not matter as this is a tutorial in style more than efficiency.

Line 10 clears the screen, this prevents the screen from getting too cluttered. A jumbled up screen is a mess! Line 20 tells the user what the program does . . . very important!

Line 30 prints two spaces, thus separating the next lot of text from the title, once more this aids in making the screen more readable.

Line 40 actually serves as two lines. It is the same as:-40 PRINT "Enter a weight in stones"; 41 INPUT S

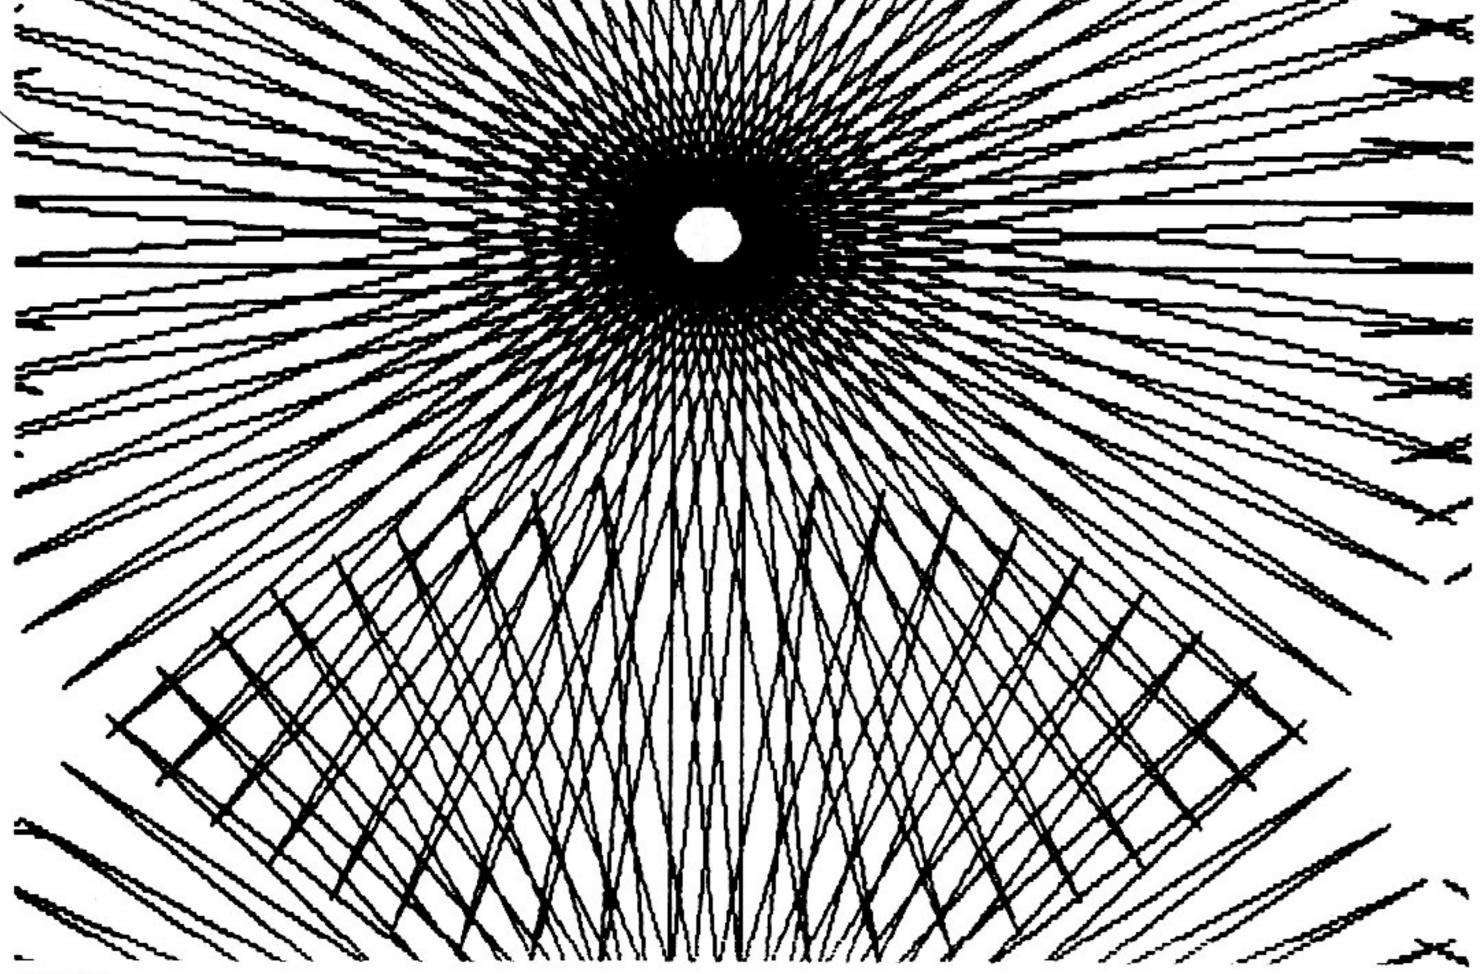

Luckily, the BASIC on the SEGA let's you group together a PRINT-PRINT sequenace, study line 40 a little more, and you'll see how it works. S will hold the value of the weight in stones.

Line 50 this converts the stones into pounds, by multiplying $\bf S$ by $\bf 14$, the variable $\bf P$ is then assigned the value of $\bf S$ times 14. Note that the * symbol is used to multiply, +, - and /, add, substact and divide respectively, but * is a little odd and serves as multiply on 99.99% of all computers. P will now hold the value of the weight in pounds.

Line 60 separates the screen a little, aiding in clarity. Line 70 this prints out the final result. Note how variables, in this case S and P, are separated from text, (the stuff inside "s) by colons (;). This is extremely important. To sum up all data must be separated from text by ;.OKAY?!!!

Line 80 The End

Well that is hopefully going to clear up a few problems that a few people are having. For any more help please write to me.

Why are most BASIC's different, I thought BASIC was BASIC and that's that!

There is no such thing as a standard BASIC. Or rather there are a number of standard BASIC's. By dint of it's popularity, the most standard of BASIC's is MicroSoft BASIC. On the other hand the standard BASIC in educational institutions in Britain is BBC BASIC. Here is a quick look at some BASIC's available on micro computers.

Microsoft BASIC is the best known dialect of the language. Commonly known as MBASIC, it is the granddaddy of nearly all home computer BASIC's. It is used in business machines such as the IBC PC and the ACT Apricot. There is a special version of the

language called version 2.0 that runs on the Apple Macintosh and makes use of it's more advanced features. More than anything the Mac is a graphics machine and the version of MBASIC that it uses is tailored to meet those needs.

MSX BASIC is directly derived from the original Microsoft dialect, as are the versions used by the Commodore micros-though Microsoft disown the awful implementation on the Commodore 64 and 128!

CBASIC is Digital Research's answer to Microsoft BASIC and can be found on a number of CP/M machines. It's special features include the ability to split a program into lots of little "lumps" or procedures thus enabling programs to be debugged a lot quicker.

ANSI BASIC is an attempt to standardize BASIC. It took the ANSI (American National Standards Institute) the worst part of ten years to define the language, and although it is very good, the world as a whole doesn't know that it exists! You can find a version of the BASIC running on a computer called the Enterprise, and it's BASIC is called IS-BASIC, or Intelligent Software BASIC.

GW-BASIC is known as "Gee Whizz" BASIC — apparently the Americans liked it when they first saw it! Underneath all the razzzmatazzz, GWBASIC is Microsoft BASIC with a few frills.

Big computers have big BASIC's. Hewlett-Packards BASIC is over 200k long! But it is designed for scientific number crunching, and has a whole host of built-in functions for complex math. DEC BASIC Plus is similar, and runs on \$5000 plus machines.

Sega BASIC has one point that kills all other BASIC's and that is the editor. If you, make a boo boo in a program it is a simple matter to correct that line, you, just move the cursor up to the line and alter it . . . simple as that! On, say a ZX-Spectrum, you, have to call up the offending line. Move the cursor to the error, which can take up to 1 minute to get to the end of a line! And then alter it . . . very time consuming. The Sega's editor is the best I have **EVER** seen!

Amstard BASIC is very powerful and fast, it supports graphics and sound very well. It also lets the user run up to 5 small sub programs at once! It's BASIC does lack a few Disc operating commands though.

On the whole, BASIC is not a portable language. That is, programs written without a few modifications. However right at the top of the heap is a BASIC called BLS, BASIC Language System, this, in theory let's the programmer write a BASIC program, and then later on, that program can be made to run on any machine . . . there is one slight draw back . . . cost, to buy BLS you more or less have to pay an arm and a leg and possibly throw in a pint of blood for good measure!

Why should a **BASIC** programmer learn Logo as a second language? What programs can be written in Logo that can't be written in BASIC?

The short answer to this is, none; but Logo is better suited to some types of progam than BASIC is, and enables you to write them more quickly and economically. Perhaps more importantly, though, is the difference in thought processes between programming in the two languages.

It's the fact that you have to think differently when you progam in Logo that underlies it's use as an educational language. Many home computer versions of Logo are designed for education use, following the guidelines put down by it's inventor Seymour Papert, and most have good manuals.

To a BASIC programmer, it can be difficult to realise how many elements of the language are optional. What! No line numbers? What! A language that need not have a program to run? Both these are true of Logo.

In Logo, you write short procedures, procedures which use other procedures which use other procedures and so on and so on. You don't use a special thing called a program, you run one of these procedures.

From another angle, you might think of each Logo procedure as the definition of a word in the Logo language. Words which you define yourself (like Forth, covered later in the magazine) — say SQUARE, or CIRCLE-once their definitions have been stored in memory, they can be used as though they were standard Logo commands.

Logo does in fact go beyond graphics, it can be used to create very powerful data bases, powerful enough to be used in artificial intelligence work. It is similar to other languages, such as LISP and Prolog in this respect.

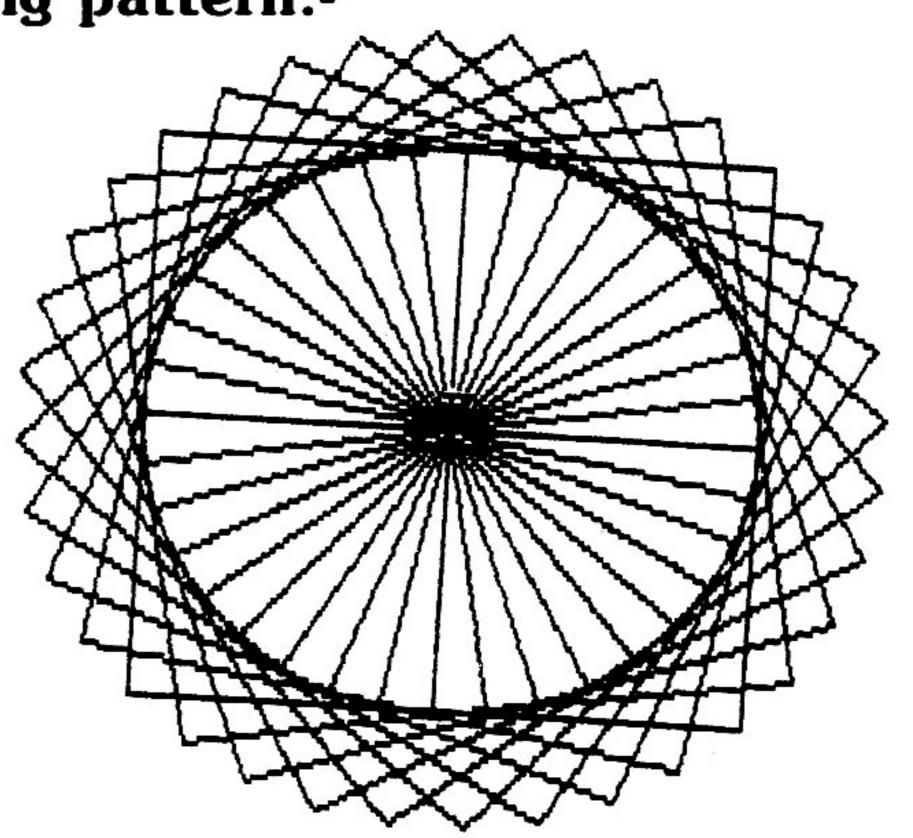

One of the very best Logo's is available, on disc for the Sega and disc drive combination, I can only say one thing, if you have a disc drive and want to learn a new and innovative language, then purchase Logo!

Here is an example program that draws a while host of boxes on the screen:-

TO BOX REPEAT 4 [FD 100 RT 90] END

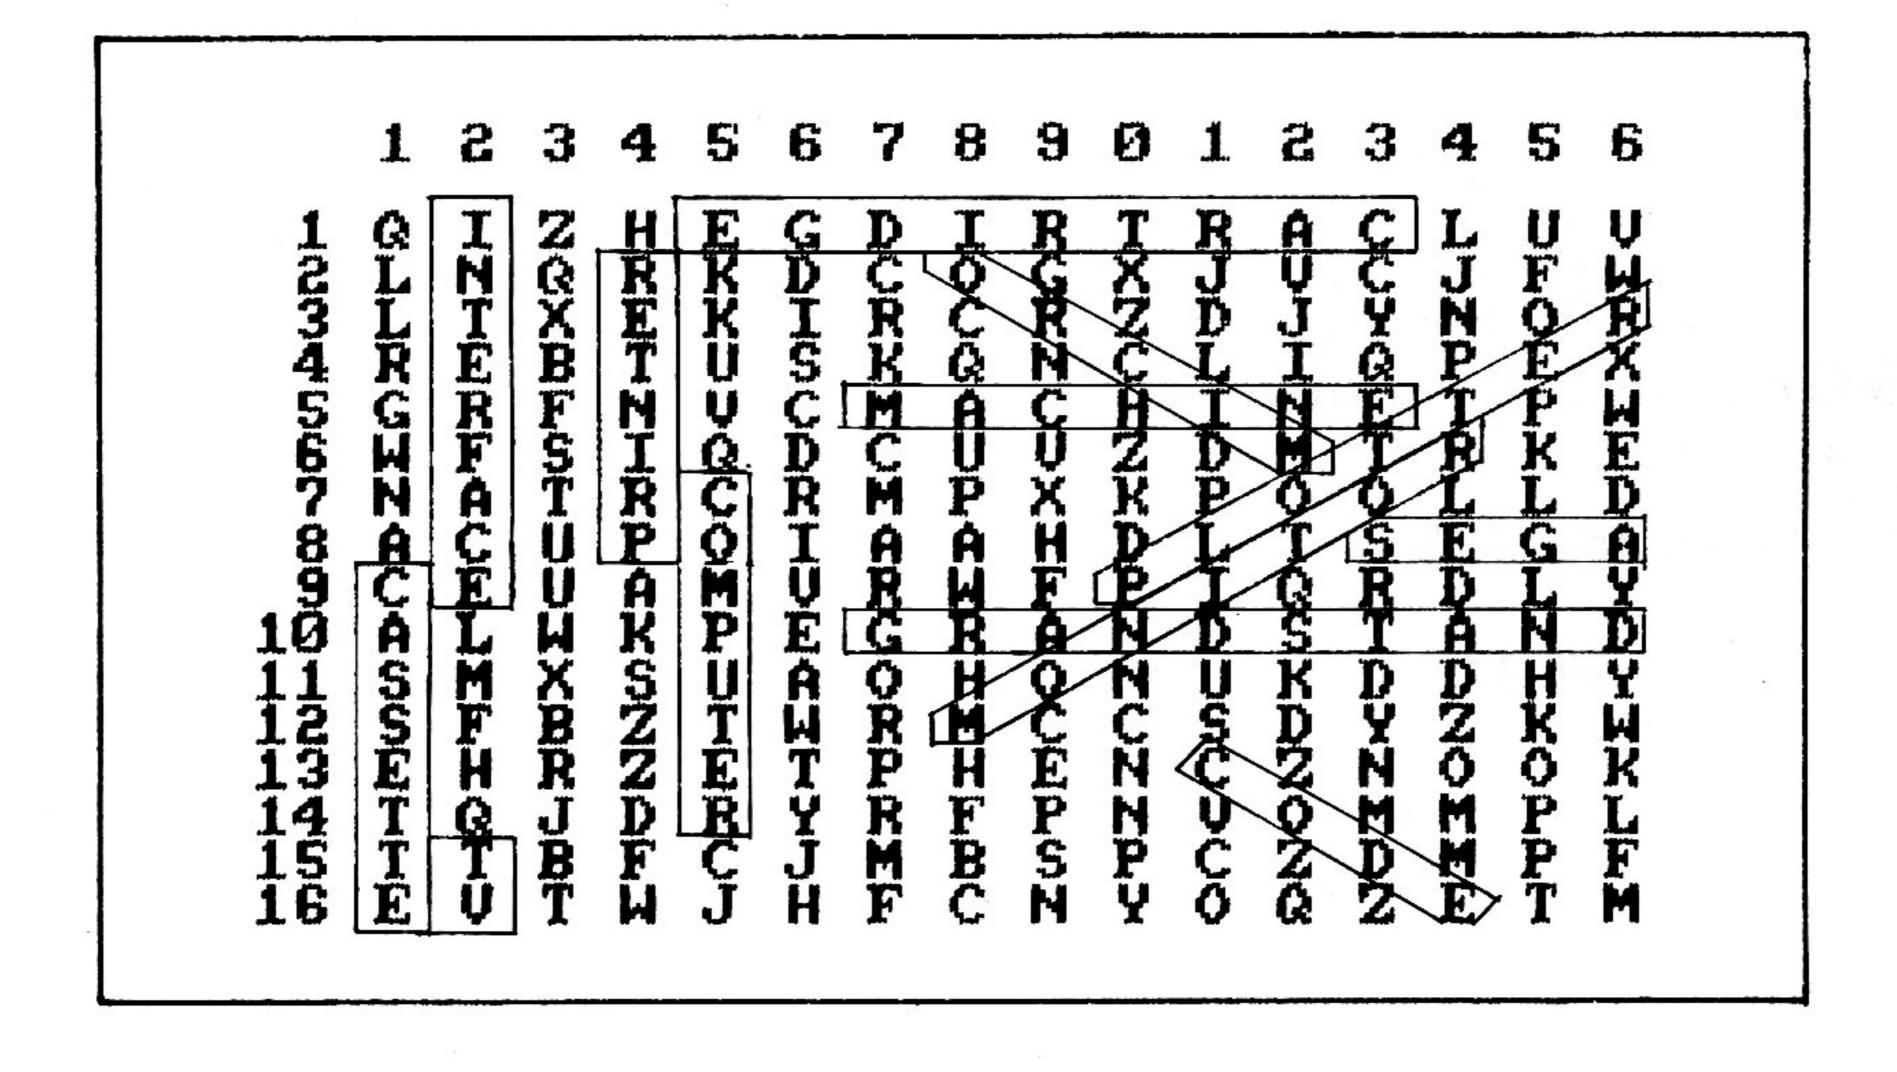

TO BOXES REPEAT 36 [RT 10 BOX] END

If, when in logo, you type Boxes, you'll get the following pattern:-

Competition . . . The Solution

Well, here is the solution to the word search:-

Basketball

In this program you play the captain of the Sega College Basketball team, and the program simulates the game really well.

You are, as I have said, the captain of the Sega team and you can control the type of shot and defence that you use through out the game.

There are four basic types of shots:

- 1) Long Jump Shot. (30ft)
- 2) Short Jump Shot. (15ft)
- 3) Lay Up.
- 4) Set Shot.

Both teams use the same defence, but you may choose it by pressing:

- 6) Press defence
- 6.5) Man to man defence
- 7) Zone defence
- 7.5) No defence

To change the defence press 0 as your next shot.

Note that the game is biased ever so slightly towards Sega College. The average probability of a Sega shot being good is 62.95% compared to a probability of 61.85% for the opponents (the computer).

Buzzword Generator

This program is invaluable for preparing speeches and briefings about educational technology. This buzzword generator provides sets of three highly acceptable words to work into your material. Your audience will think that you must be some mega brain as you verbally throw up this garbage! And they will never know that the phrases don't actually mean anything because they sound so great!

To run the program just read through the program.

```

3D Noughts and Crosses

3D Tic-Tac-Toe, call it whatever you like, is the game of normal Tic-Tac-Toe on a 4x4x4 cube. You must get 4 markers in a row or diagonal along any 3-dimensional plane in order to win.

Each move is indicated by a 3 digit number (digits not separated by commas), with each digit between 1 and 4 inclusive.

The digits indicate the level, column and row respectively, of the move. You can win at this game, but only if you play really well, as the game is considerably more difficult to plat than conventional 3x3 Noughts and Crosses.

```

```

The Forth Programming Language

By Michael Howard

Many of you probably know how to program in BASIC, and although this language is often put down by critics as a lousy programming language it is in fact a very good and complex tool.

All programming languages have their advocates, my pesonal favourites being Pascal, C and this one . . . FORTH. Few devotees are as impassioned (crazy!) as those who support FORTH. FORTH is incredible flexible, fast (typically 20 to 30 times faster than an equivalent BASIC program), and very, very compact (in other words a FORTH program will take up very little memory). So I thought it would be a good idea to develop a way of letting Sega owners get the taste of FORTH without having to buy the language. The program that follows let's you mess about with FORTH, but remember, it is not a full FORTH, and it is very slow, because it is written in BASIC.

The following program is approx. 9k long, so it is a bit of a typing chore, but when you consider that you end up with a new language (for free), the effort is more than worth while, In fact a friend of mine, who I let test the program, (so that I could get constructive criticism and help with the debugging) does nothing all day except play with this FORTH emulator!

The FORTH programming languages was developed by a gentleman by the name of Charles Henry Moore, he found that the languages of the day could not do what he wanted them to do, so he invented his own. The computer he was working on was called an IBM 1130, and in the 1970's these beasts were the "ultimate in computers!". Moore believed he had developed a Fourth Generation Language (BASIC is Third and a half generation!) so wanted to call the language "Fourth," but unfortunately the IBM would only allow program names to be of 5 or less digits in length, so Moore had to change the name to FORTH! This is a true story!!!!

FORTH differs from many other languages, such as BASIC, because it comes with a standard set of words which the programmer can use to develop his or her own commands, which makes FORTH fast, freaky, functional and flexible (what a mouthful!!) and trendy!

However, as the authors of the book "FORTH" (Salmon, Tosserand and Toulout; Macmillan, 1984) point out, this flexibility means that FORTH can in fact be written in FORTH!! This emulator won't let you do that, but it will let you create up to 500 new words, which the system will execute as though they were programming words provided by the raw version of the language.

Reverse Polish Notation . . . RPN

One of the more unusual features of FORTH is it's arithmetic. When you want to add two numbers together, say 42 and 69, in BASIC, you would enter the following:-

PRINT 42 + 69

In FORTH you'd need to enter:-

42 69 +.

You enter the first number, then a space (spaces are really important in FORTH, as you'll see soon), then the second number, then the operation you wish to perform, in this case +, then follow it by a dot, this tells FORTH that you want the result of the calculation to be printed out. If you, omit this dot, FORTH will still work out the value, but it won't print it on the screen. This kind of arithmetic, working from left to right, is called Reverse Polish Notation.

The Stack

The stack is one of the most fundamental principles of FORTH, so it is well worth the effort of trying to understand what it is and how it works (another reason for learning how it works, is because in the future, when you start to learn Machine Code, you'll have to be able to manipulate the stack . . . and what you learn here will be applicable to the Machine code environment).

The stack is like a tall mound of paper. You can only add or remove pieces from the top of the stack of paper, and the last piece of paper you put on the pile, will be the first to be taken off.

When you enter the number 42 followed by a space, a computer running FORTH effectively writes this number onto a piece of paper and places it in the top of the stack of paper. It then writes the next number (69) onto a piece of paper, and puts that on the top of the stack of paper, so now, 69 is on the top of the pile, whilst 42 is second to the top . . . think about it a little.

The computer then comes up to the "+" instruction, which is a word in the computer's 'dictionary' of words, "+" tells the computer to take the top two numbers from the top of the stack, add them together, then place the result onto the top of the stack. This is what **42 69** + does. Finally, when FORTH bumps into '.', the computer prints the result out. The dot means take the value off the top of the stack and print it out.

As I said earlier, if you don't include the dot command, the computer will still work out the problem, but will leave on the top of the stack.

Making the Stack visible

The stack provided with my program can be up to 20 'sheets' of paper deep. The sheets can only store numbers, and as we saw before, a number is written on the top sheet, then the sheet which used to be at the top is now second, the sheet that was second is now third and so on . . . The program let's you see the top four elements of the stack, called a 'Visible Stack', so you can see what is going on.

When you first run the program, you will be asked if you want to have the stack printed out, if you say YES, then after each round of instructions, the stack will be displayed on the screen, thus:

Stack:

1..-

2..--

3..--

4..--

Ok

The double minus sign '--', means that the stack is empty at the point (or if you like, the sheet of paper is blank). You can prove this by entering a dot (.) after the OK appears. This, you'll recall, is to print out the top element of the stack. When the stack is empty, as in this case, you'll get a **Stack Empty** error. So let's have a bash at working out our little sum, and taking a look at the stack whilst the program is running.

When the Sega comes up with the Ok message, it means that it is ready to accept a command, somewhat similar to READY in BASIC. Type in the following sum, making sure you put spaces between each 'Word':

42 69 +

After a short pause, you'll get the answer back (111). As you can see the command has all been entered on one line, to see what the stack is up to, we'll have to break down the command into sub-commands, ie 42 69 + . is made up of four instructions, 42, 69 + . and . so we could do the following instead:-

- 1) Type in 42 now press the CR key.
- 2) Type in 69 now press the CR key
- 3) Type in + now press the CR key.
- 4) Type in . now press the **CR** key.

You'll notice that at each stage the stack alters.

When you press 42, the stack will look like this:

Stack:

- 1..42
- 2..--
- 3..--
- 4..--

Ok

You can see 42, at the top of the stack.

When you, enter 69, the stack will look like this:

Stack:

- 1..69
- 2..42
- 3..--
- 4..-

Ok

Notice how the 42 has been PUSH'ed down and 69 is placed on the top. Now when the + is encountered, a strange thing happens, firstly the top two numbers on the stack are removed and then added together, the

result is then put at the top the stack, don't forget that the top two numbers have now been removed. After the + operation the stack will become:

Stack:

- 1..111
- 2..--
- 3..--
- 4..--

Ok

In other words . . . empty!

Now, just mess about with a few simple calculations and take a look at the stack after each command, but don't forget those spaces!!! and mess with /, +, -, and *.

All FORTH operations boil down to PUSH'ing onto the stack, and POP'ing it off.

Defining Your Own Words

The most exciting thing about FORTH is the ability to create your very own new words, and we'll look at this next.

You'll recall, from the earlier arithmetic examples you've tried that the dot is used to pop the top value off the stack and print it on the screen. There may be times when you want to print out the value but still want the value on the top of the stack to stay there. Dot, as you have seen is destructive-you lose the top number on the stack by popping it off.

The word DUP (for 'DUPlicate') gets around this little problem by duplicating the value at the top of the stack onto the top of the stack, in other words, if the stack looks like this:

Stack:

- 1..20
- 2..--
- 3..--
- 4..--

Ok

Then after DUP, the stack would become:

Stack:

- 1..20
- 2..20
- 3..--
- 4..--

Ok

See what has happened, the number 20, has been duplicated, So now you could pop the value of the top of the stack and leave a copy of that number on the top of the stack.

We can invent a word of our own, PRINTOUT, to duplicate the number on the top of the stack and print it out. You create words, by using the following format:-

: Program Body ;

Note that a ':' starts off the definition of a new word, and a ';' ends the definition.

So our word PRINTOUT, would be:

: PRINTOUT DUP . ;

(note the spaces)

In this example, we start off with a colon, follow it with a space, then the program body (DUP .) followed by a space and then semicolon.

From this point onwards you, can simply use PRIN-TOUT in your FORTH Programs, and your computer will automatically perform the **DUP**. for you. The program, as it stands, allows you to create up to 500 new words.

Here is another word:

: SQUARED DUP * . ;

In this example, whenever we call SQUARED, the number on the top of the stack is duplicated, the top two numbers (the same number) are multiplied together and the result is printed out. Here's an example: If we said 4 SQUARED (don't forget, the 4 has to go on the stack before SQUARED is used) we would get an answer of 16. Here is how it works:

1) 4 is put on the stack. The stack now looks like this:

Stack:

- 1..4
- 2..--
- 3..--
- 4..--
- 2) SQUARED is now invoked.
- 3) The first instruction in SQUARED is DUP, so the stack is now:

Stack:

- 1..4
- 2..4
- 3..--
- 4..--

4) The next instruction in SQUARED it is *, so the top two values on the stack are removed and multiplied together, the answer is then put on the stack. The stack is now:

Stack:

- 1..16
- 2..--
- 3..--
- 4..-

5) The next part of SQUARED instruction is . which prints out what is on the top of the stack, in this case 16 is on the top, so 16 is printed out, and the stack is left bare.

Imagine if we wanted the value of 4 SQUARED (16) to be left at the top of the stack, we could write this:

: SQUARED DUP * DUP . ;

The 'DUP *' bit does the usual bit, the 'DUP .' bit makes sure that the value at the top of the stack is printed out, but only after a copy is made.

Now this is where the beauty of FORTH comes into it's own, if we'd already defined PRINTOUT as **DUP**. then we could alter out new SQUARED program to:

: SQUARED DUP * PRINTOUT ;

See what is going on, PRINTOUT has replaced DUP . good stuff eh?!?!

FORTH always uses the most recently defined version of a word, searching it's dictionary from the newest word to the oldest, so you can safely redefine a word and know that it will use the latest version.

You can see a hint of real magic of FORTH in this inclusion of PRINTOUT within SQUARED, you could define lots of words and include them in newer words as oftens as you like!! This is the sheer power of FORTH!

To forget a word from the dictionary, type in FORGET followed by the word to forget, but be warned that when you, do this FORTH will also forget all the newer words defined after the word you told it to FORGET!

Forth in action

Forth works in more or less in the following way:

- The user types in something into the computer after the OK prompt.
- FORTH looks through it's dictionary of words to see if any of them match the word which has been entered.
- If it finds a match, either within the dictionary provided with the program, or within the dictionary of words the user has provide, it executes the word then goes to the next element in the input.
- If it doesn't find a match, it assumes the word is a number.
- If it isn't a number, then you made a mistake.

You'll find that this program is well furnished with error messages, which (along with the visible stack) should make it pretty easy to keep aware of what is going on in the program.

NOTE: Very few, if any, FORTH compilers give a visible stack.

The usefulness of being able to define words is illustrated by the following examples. Suppose you want a word called CIRCLE, which would take a number off the top of the stack, and treat it as the diameter of the circle, you'd only need to enter something like 23 CIRCLE to get your Sega to print out the circumference of a circle with a diameter of 23 units.

The word CIRCLE could be defined as follows (where 355/113 is an integer approximation of PI, since most FORTHs work in integers, rather than floating point numbers, such as 1,1.3.1415926536 etc):

: CIRCLE 255 113 * / . . 'IS THE CIRCUMFERENCE';

This works by multiplying the value on the top of the stack by 355, this new value is then divided by 113, this result is then printed out, followed by the message IS THE CIRCUMFERENCE.

The new words in this are:-

* multiply

/ divide

.'print out a string of letters, Eg;.'HELLO' would print out HELLO, note the spaces.

If you made the above word, then all that you would have to do is enter a number (or let the computer take a number off the top of the stack) for the diameter and the computer will do the rest. You'll find that you'll have a lot of fun defining all your own words and using them in your programs.

The built in Vocabulary

There are two widely used 'standard' versions of FORTH, fig-FORTH (From the Forth Interest Group) and FORTH-79. The program that I have provided sticks mostly to the Forth-79 standard, but there are a few Fig-Forth equivalents, such as Fig's MINUS and 79's NEGATE are both supported, and they are the same.

The vocabulary supplied with the program is quiet extensive, but by no means complete. I will now explain each word provided.

+,-,/ and * these all take two numbers off the top of the stack and operate on them, eg add, subtract etc and then push the result onto the stack.

/ and MOD these are the same in that they divide, but / puts the quotient on the top of the stack, and MOD puts the remainder on the stack. As an example 11/5, the quotient is 2 (5 goes into 11 twice) and the remainder is 1. So 11 5 / would leave 2 on the stack 11 5 MOD would leave 1 on the stack.

/MOD is one word and puts the quotient and remainder on the stack, with the quotient at the top.

- */ is, once again, one word. It multiplies, then divides leaving the result on the top of the stack. Note that this requires 3 numbers on the stack before the command is used.
- */MOD is similar to */, returning the quotient and remainder, with the quotient on the top.
- ** takes two numbers from the top of the stack and raises the second number to the power of the first one on the stack, returning the result on the stack.

NEGATE and MINUS take the top number off the stack, and make it negative, the value is then put back on the stack.

ABS is the same as BASIC's ABS, it takes the value off the top of the stack, take sthe absolute value (eg 10 becomes 10, -11 becomes 11, -42 becomes 42 etc.) and places it on the stack.

MAX and MIN compare the top two numbers on the stack, leaving only the largest (MAX) or the smallest (MIN) behind.

DUP we have already met this, it duplicates the top of the stack, so where there is one value on the top of the stack, you get two.

?DUP is similar to DUP, but the duplication is made only when the top of the stack is not zero.

OVER takes the second element on the stack, and

copies it over to the top of the stack. So if the stack looks like this:-

Stack:

1..16

2..88

3..--

4..--

Then after OVER, the stack will become:-

Stack:

1..88

2..16

3..88

4..-

See how 88 has been copies to the top of the stack thus pushing 16 and 88 down.

PICK must be preceded by a number. This command selects the numbered element on the stack and copies it to be top of the stack. So if you type 3 PICK, the third element will be copied to the top of the stack.

DROP deletes the top element from the stack, and moves the rest of the stack up.

SWAP causes the top two numbers on the stack to change places.

ROT brings the third element on the stack to the top, whilst the top two are moved down a peg. Eg;

Stack:

1..16

2..55

3..98

4..--

Becomes, after ROT:

Stack:

1..98

2..16

3..55

4..--

ROLL like PICK, must be preceded by a number. It brings this numbered element to the top of the stack, deleting it from it's original position. All the other elements move down a peg.

VLIST lists all the words that the computer knows.

FORGET must be followed by a name, every word defined after this word is deleted from the dictionary. This should be used only with caution.

KEY works just like INKEY\$ in BASIC. It waits until you press a key, and that key value is stored on the top of the stack. So if you press the space bar, 32 will be stored on the stack. Check your ASCII table of characters in the users manual.

. (dot) this prints out, as a number, the top value on the stack.

.' (dot quote) this must be followed by a space, and then followed by some text. Eg.' HELLO ESTER' will print out HELLO ESTER.

'(tick) prints out the description of a word, so 'PRIN-TOUT will give you all the commands that make up the word PRINTOUT.

EMIT prints out the ASCII character of a number, so 42 EMIT will print out an asterisk.

SPACES can be used to print out spaces, so 10 SPACES will print out 10 spaces!

CR will move the print output to the next line down. **DO . . . LOOP** is similar to FOR . . . NEXT in BASIC. It repeats everything between DO and LOOP. The number of repetitions is the difference between the top two numbers on the stack. If 11 were on the top of the stack, and 1 the next number down, then the loop would run for 10 times.

You're bound to have met **IF** . . . **THEN** from BASIC, and even though they do in fact perform the same function, the FORTH version may appear to be a little wierd, to say the least!

The condition being tested comes before the IF, and if the condition is true then all the commands between the IF and THEN are executed. If it is false then the commands after the THEN are executed. IF/THEN in FORTH can evaluate =, > </< as well as check if a number at the top of the stack is equal to, not equal to, greater than or less than zero.

The word **NOT** causes the IF/THEN to look in the opposite direction.

Finally, in our standard vocab there are some special arithmetic words to add one to the number on the top of the stack (1+), or subtract one (1-), the other commands are 2-, 2+, 2/ and 2^* .

I have also put some non-standard words in, like **STACK** to turn the viewing stack on or off. If the stack is on then after a STACK word, then stack will be turned off and vice versa.

ABORT quits an action.

LLIST will list all the words in the memory and their descriptions.

To help clear up a few of the mysteries, here are some programs.

The first of which is a game of "Guess my Number". The computer thinks up a number between 10 and 100, and you are given 10 chances at guessing the number.

The game itself, is held in the word GAME, this in turn uses other words, which in turn uses other words etc.

The program may look quite complex, but if you take it to bits and play about with FORTH for a while it'll all click.

To run the game just enter GAME, but only after you have entered the program words.

: GAME THINKNUM 11 1 DO GETGUESS TEST LOOP END;

: THINKNUM 90 10 RAND ;

: GETGUESS CR. 'Enter guess' KEY 48 — KEY 48 — . 'Ta!' SWAP 10 * + ;

: TEST SAME? BIGGER? SMALLER? DROP;

: END . 'Sorry. Time is up!' CR . 'I was thining of' .; : SPINNER DUP ROT DUP ROT;

: SAME? SPINNER = IF. 'You did it!' ABORT THEN.

: BIGGER? SPINNER > IF . 'Too big 'THEN; : SMALLER? SPINNER SWAP < IF . 'Too small' THEN SWAP;

This next program is simple:-

: STAR 42 EMIT ;

: STARS 11 1 STAR 11 1 DO STAR LOOP;

Now whenever you enter STARS, you will get a row of 10 stars.

Try experimenting. I will love to hear from anyone who really takes to FORTH and decides to write a few simple programs, I will be more than happy to publish them in the magazine, and perhaps even set up a little FORTH interest group, but that of course depends on you!

I hope you like it.

How to check for a bias dice

If any of you out there are into playing role playing games such as **Dungeons and Dragons** then you will know just how often a die seems to yield a high number when you need one, and a low number when you need one. This is usually in the mind of the player, but sometimes a die can in fact be bias towards one number, and the way to check for it is by using a standard test called **The Chi-square test**. Now this test is really 'orrible and mathematical, and I won't go into too much depth about it, so all I'll say is that Chi-square is a way of testing any statistical date for randomness.

How to do it:-

Enter the program listed below. The program, when run, will ask you to enter the number of faces on the die, this will usually be 6 sides, unless you are Role Player in which case the number of sides could be 4, 6, 8, 10, 12 or 20.

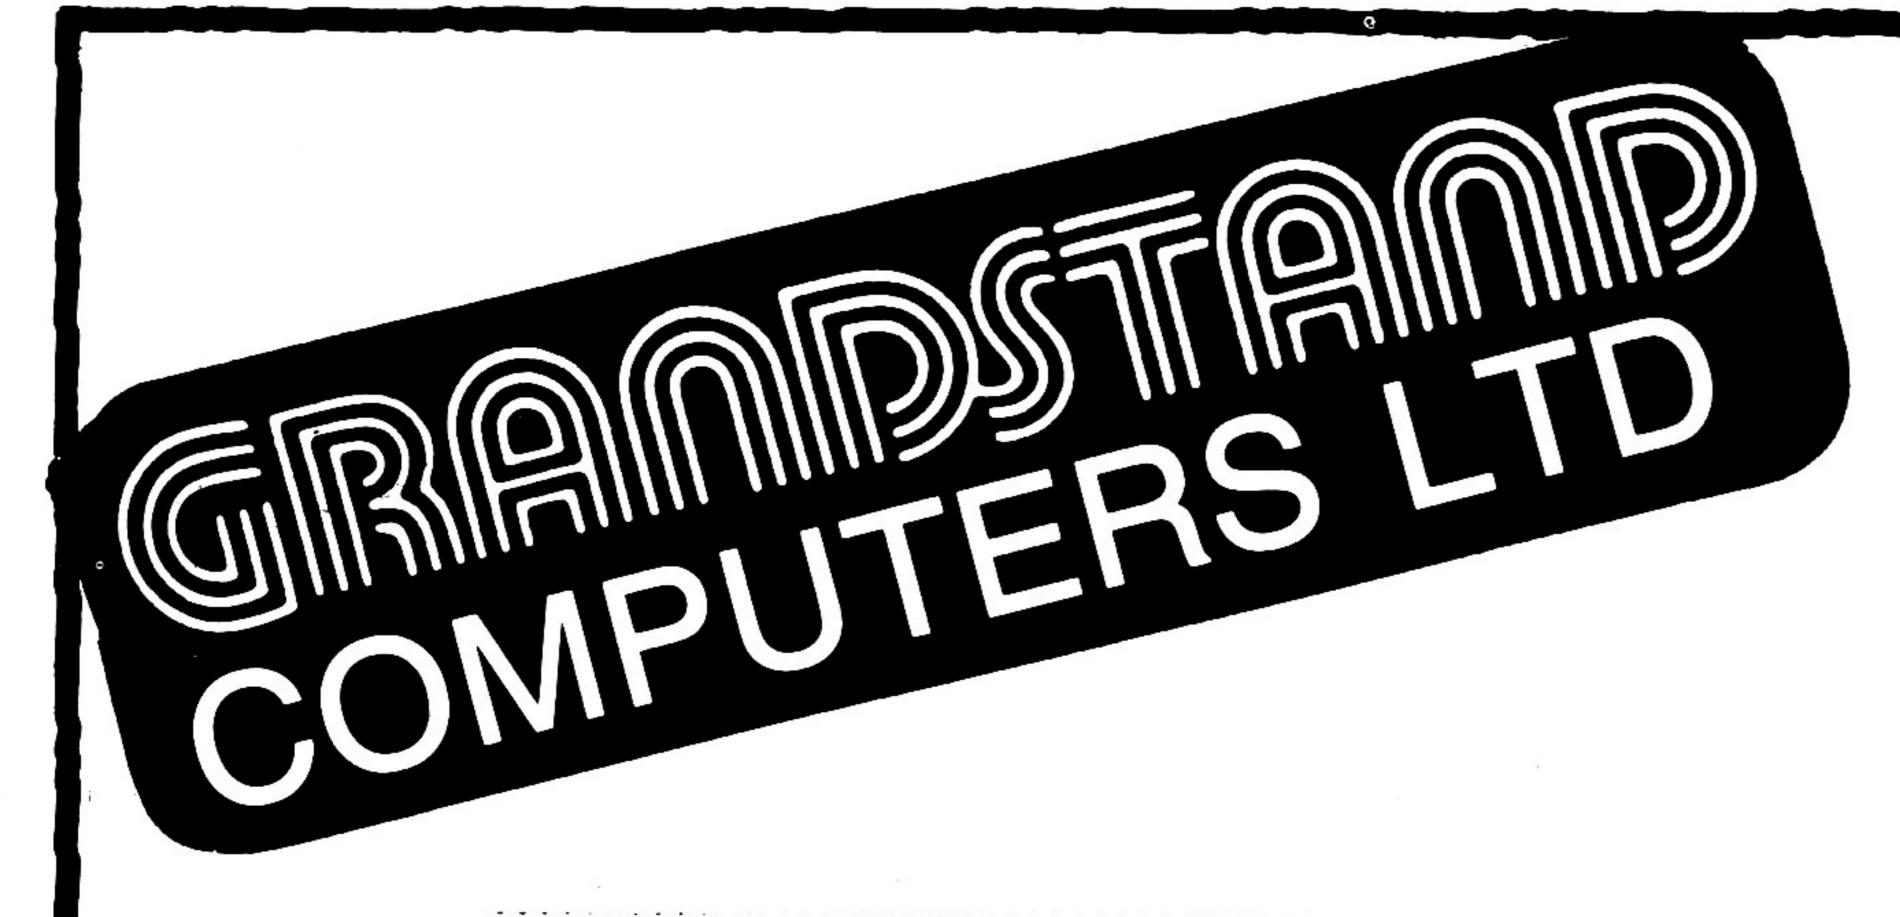

The computer then asks you for a value of E, this is the expected number of times a face will occur, so if you enter say 10, and the dice is 6 sided then after 60 rolls, each face should appear 10 times, if the dice is completely unbiased. Note that if you enter a number less than 10 for the value of E, then the computer automatically sets the value of E to 10.

The program then asks you if you want to categorise the groups, in general answer with a 0, at this stage.

The next step is entry of data. Roll the die and enter the results until the computer tell's you to stop. If you enter an invalid number, such as a 7 when you are using a 6-sided dice, the computer tells you that you've made a mistake and asks you to enter that value again.

Finally, the value of the Chi-square will be given along with a message indicating the level of bias.

```

How to Make Limitless Mazes

... Michael Howard

Many excellent games are marred by a limited capacity for storing mazes and the computing time required to set up the data at the start of each run of the program. When details of each game are stored away as data, a lot of memory is taken up, and this memory could be used to make the game a lot better.

There are ways, however, to overcome this problem so that even a humble 16k Sega can guide the games player round labyrinths which are large enough to tax the most hardened games player.

THE TRICK

The trick to getting a very large maze into a small computer is to store the details of the maze in a mathematical equation. Suitable functions already exist to create random numbers, in fact the random number generator in your Sega is nothing more than an equation! To generate a random maze, that is infinite in EVERY director, and is totally mappable can take up less than 1.5k of memory by using a special function!

Mazes are two or in this case three dimensional structures which can be defined by random functions of two or three co-ordinates. The function indicates whether any given location is open corridor or solid wall. If the location is defined by co-ordinates X,Y and Z, then these values can be passed onto a special function and that function dictates whether walls or corridors exist at those co-ordinates.

The function I chose to dictate the maze is the following:

9000 U = 100 * SQR(X * X + Y * Y):W = U - INT(U)

In this program, a special variable called T is allocated, and this dictates how the maze looks, by altering this value, the maze can be totally re-arranged in an instant. In the program below, you can scatter objects around by saying "If the player is at point X, Y and Z then he/she has found a pot of gold, where X,Y and Z are some numbers determined at the start of the game.

Okay, onto the game. At the start of the game T is set a value of 0.3, this sets the maze to a certain shape, if you alter T to some other value then the maze will be different. Next you are told what is around you, and asked for a command. At first you are on the surface, you can only go down into the maze if you meet a shaft, when you go down you are in the maze proper. There are some very deep mines, but you can map the whole area and get out of any situation. Here lies the beauty of this technique: by using various functions of the type described, you can invent your own structures and explore them without knowing in advance what you will find!

It will be interesting to see what sort of programs you budding programmers come up with, now that I have laid down the foundations for a really exciting method of data storage in adventure games. So come on, develop some programs around this technique or else the Troll will get you!

A look at the ADVENTURE game

... Michael Howard

Of all the computer games that are availbale on the Sega, and many other computers for that matter, none seems to have gained the popularity that Adventure games have, save for "Space Invaders"!

What is "ADVENTURE"?

Well, let me start at the very beginning. Many years ago,

a man called Gary Gygax invented a game called "Dungeons and Dragons", and many people (me included!) got caught up in the atmosphere of role-playing. Dungeons and Dragons was the first role playing game in which players assume alter egos and use them to wander through strange, exotic lands or caves and encounter many monsters and strive to accumulate wealth while building up his/her character. Dungeons and Dragons has it's origins in JRR Tolkien novels, such as "The Hobbit", "The Lord of the Rings" and "The Silmarillion".

These games usually have a "Dungeon Master" who does not actually participate in the game. He or she has a detailed map of the dungeon, and charts the players progress (and other nasty creatures) through it. The players tell the Dungeon Master where they wish to go, and the Dungeon Master describes their new location in great detail, along with objects they may see. If a confliction with a creature takes place, the Dungeon Master rolls dice to simulate the random element in any conflict, and after weighing up such factors as what weapons are being used, how strong the fighters are etc — the result of the conflict is announced. As you can

see there are few limitations to the game and some games last for ages. (One game, of which I am the Dungeon Master, has lasted over 2 YEARS!!!).

When computers came on the market and became popular, a gentleman by the name of Will Crowther decided to write a game that simulated the Dungeons and Dragons situation, with the computer being the Dungeon Master. The program was written in a now archaic language called "Fortran" and was called, quite simply, Adventure. The program was released in 1976 and was added to the "DECUS" library, (the DECUS library is for DEC PDP-11 (a large computer!) users) and library. The game was so popular that people were phoning up the programmer at 3am to ask how to get over the Troll's bridge.

Unfortunately, in those days, games such as Adventure needed extensive disc backup, owing to the lack of onboard memory. Well, now computers have quite large memorys and are designed perfectly for adventure games.

Luckily, we now have quite a few adventure games available for the Sega, thanks to the likes of Flexisoft, Scorpion Software and Poseidon Software, and we have a few left. So hopefully, this little section will spark some interest in such games.

The games to look at are The Youngins, TTS, Transylvania Castle of horror, Underworld of Kragon, Castaway, The House! And others.

So get stuck in!

This program is a simulation of the card game Acey Ducey. In the game, the dealer (in this case the computer) deals two cards face up. You have an option to have a value between the first two.

Your initial money is set to \$100. The game continues until you are skint or you switch the power off! Here goes \dots

```
10 CLS:PRINT "ACEY DUCEY": X=RND(-1)

900 PRINT
910 PRINT "SORRY, YOU'VE NO MONEY LEFT!!"
```

610 PRINT "YOU'LL BE LUCKY, YOU DON'T HAVE THAT MUCH!"

Crazy Cancellation . . . More maths fun!!

Last months little maths program showed that maths is great fun on computers (well sometimes!), and suprisingly, quite a few people wrote to me asking for more maths fun. So I decided to oblige!

The following program finds incidences of coincidentally correct cancellations! What-a-mouthful! Basically, all that means is . . . well let me show you an example:-

16/64 = 1/4, by cancelling the sixes . . . see what I mean!?

```
\frac{\chi^{2} + 7\chi + 12}{\chi^{2} + 4\chi 3} = (\chi + 1)(\chi + 3)
```

Not only is the maths correct, but the fact that some common numbers can be cancelled and still produce the same result . . . is quite amazzzzzing!

Oh by the way, fractions such as 10/20 and 20/30 are ignored because they are obvious and thus very, very boring!

All the fractions are less than 1. One of the main drawbacks of the program is that it is very slow.

```
Here is the program:
```

```
1 REM MH
10 er = 0.0001
20 FOR t = 1 TO 9
30 FOR u = 1 TO 9
40 FOR a = 1 TO 9
50 FOR b = 1 TO 9
60 IF t < >a AND t < >b AND u < >b THEN 240
70 nu = 10*a + b
80 de = 10*t + u
90 IF nu > de THEN 130
100 b = 9
110 a = 9
120 GOTO 240
```

```
130 q = nu/de

140 e1 = ABS(qpa/t)

150 e2 = ABS(q-a/u)

160 e3 = ABS(q-b/t)

170 e4 = ABS(q-b/u)

180 IF a = t AND e4 < er THEN 230

190 IF a = u AND e3 < er THEN 230

200 IF b = t AND e2 < er THEN 230

210 IF b = u NAD e1 < er THEN 230

220 GOTO 240

230 PRINT nu;"/";de; "is a solution."

240 NEXT b

250 NEXT a

260 NEXT n

270 NEXT t
```

Olympic Boxing

ng Soaches one of the boxers and deter-

This program simulates a boxing match of three rounds. The computer coaches one of the boxers and determines his defences and best punches, while you do the same for your boxer. At the start of the match, you must specify your boxer's best punch and his vulnerability.

There are approximately seven major punches per round, although this may be varied by line number 250. The best of 3 rounds wins the championship.

```

Bowls

This is a simulated bowling game for up to four players. You play ten frames.

Gutter . . . the ball went down the gutter!

Strike . . . congratulations!

Spare . . . you made a boo boo!

To roll a ball, you simply type 'roll'. After each roll, the Sega will show you a diagram of the remaining pins, a 'O' represents a pin still standing, and the computer will give you the folliwng analysis:

```
Error . . . this only happens if you made two rolls and missed on both ocassions.

The Bouncing Ball . . . a study of Kinematics

This program tests your fundamental knowledge of kinematics. It presents a simple problem: a ball is thrown straight up in the air at some random speed (velocity). You then must answer three questions about the flight of the ball:

1. How high will it go?

310 PRINT: RETURN

- 2. How long until it returns to Earth?
- 3. What will be it's velocity after a random number of seconds?

The computer evaluates your performance; within 15% of the correct answer is considered close enough. After each run, the computer gives you another problem until you RESET or BREAK the program.
